# 1 Introduction

**Definition 1.1** (Optimization Problem). 

---

Generally, an optimization problem is defined as follows:

$$\begin{aligned} & \text{minimize : } f_0(x) \\ & \text{subject to : } f_i(x) \leq 0, \quad i = 1, \dots, m \\ & \quad \quad \quad h_i(x) = 0, \quad i = 1, \dots, p. \end{aligned} \tag{1}$$

Where we have:

1.  $x \in \mathbb{R}^n$  is the optimization variable.
2.  $f_0 : \mathbb{R}^n \rightarrow \mathbb{R}$  is the objective (cost function).
3.  $f_i : \mathbb{R}^n \rightarrow \mathbb{R}$  are inequality constraints.
4.  $h_i : \mathbb{R}^n \rightarrow \mathbb{R}$  are equality constraints.

**Definition 1.2** (Convex Optimization Problem). 

---

An optimization problem is a **convex optimization problem** if:

1.  $f_0, f_1, \dots, f_m$  are convex.
2. Equality constraints are affine.

The reason why we need convex optimization problems are:

1. Convex optimization problems can be solved optimally (no local minima).
2. Time required to solve convex optimization problems is polynomial (in terms of number of variables and constraints).

## 1.1 Convex Sets

**Definition 1.3** (Lines). 

---

Let  $x_1, x_2 \in \mathbb{R}^n$ . A line passing through  $x_1, x_2$  is defined as:

$$L(x_1, x_2) = \left\{ x \in \mathbb{R}^n : x = \theta x_1 + (1 - \theta)x_2, \theta \in \mathbb{R} \right\}. \tag{2}$$

When  $\theta \in (0, 1)$ , we restrict the line to the points between  $x_1$  and  $x_2$  (exclusive).

**Definition 1.4** (Affine Sets). 

---

An affine set contains its elements' **affine combinations**: If  $x_1, \dots, x_k$  belongs to an affine set  $A$ , then it contains the affine combination

$$\sum_{i=1}^k \theta_i x_i \in A, \quad \theta_i \in \mathbb{R}, \sum_{i=1}^k \theta_i = 1. \tag{3}$$

For example,

1. An empty set is affine because there is no point.
2. A singleton is affine because there is only one point.
3. A line (extends indefinitely) is affine.
4. Any vector space is affine.
5. Linear subspaces of a vector space is affine.

**Definition 1.5** (Convex Sets). 

---

A convex set contains its elements' **convex combinations**: If  $x_1, \dots, x_k$  belongs to an affine set  $A$ , then it contains the convex combination

$$\sum_{i=1}^k \theta_i x_i \in A, \quad \theta_i \in [0, 1], \quad \sum_{i=1}^k \theta_i = 1. \quad (4)$$

For example,

1. Norm ball  $\{x : \|x\| \leq r\}$  for a given norm  $\|\cdot\|$ , radius  $r$ .
2. Hyperplane  $\{x : a^\top x = b\}$  for given  $a, b$ .
3. Halfspace  $\{x : a^\top x \leq b\}$  for given  $a, b$ .
4. Affine space  $\{x : Ax = b\}$  for given  $A, b$ .

**Definition 1.6** (Convex Hull). 

---

Given a discrete set  $C = \{x_1, \dots, x_k\}$ . The convex hull of  $C$ , denoted  $\text{conv}(C)$ , is the set of all convex combinations of points in  $C$ :

$$\text{conv}(C) = \left\{ \sum_{i=1}^k \theta_i x_i : x_i \in C, \theta_i \geq 0, \sum_{i=1}^k \theta_i = 1 \right\}. \quad (5)$$

Convex hulls are always convex.

## 1.2 Convex Functions

**Definition 1.7** (Convex Function). 

---

A function  $f : \mathbb{R} \rightarrow \mathbb{R}$  is convex if

- (i)  $\text{dom } f$  is convex.
- (ii)  $f(\alpha x + (1 - \alpha)y) \leq \alpha f(x) + (1 - \alpha)f(y), \forall x, y \in \text{dom } f, \alpha \in [0, 1]$ .

A function  $f$  is concave if  $-f$  is convex.

**Definition 1.8** (Strictly Convex Function). 

---

A function  $f : \mathbb{R} \rightarrow \mathbb{R}$  is strictly convex if

- (i)  $\text{dom } f$  is convex.
- (ii)  $f(\alpha x + (1 - \alpha)y) < \alpha f(x) + (1 - \alpha)f(y), \forall x, y \in \text{dom } f, \alpha \in [0, 1]$ .

A strictly convex function implies a unique global minimum.

**Test for Convexity of Function:** We have the following tests for the convexity of any (real-valued vector) functions.

1. Second-order derivative test.
2. Restriction to a line.
3. Epigraph.

### Proposition 1.1: Restriction to A Line

A function  $f : \mathbb{R}^n \rightarrow \mathbb{R}$  is convex iff  $g : \mathbb{R} \rightarrow \mathbb{R}$ , defined as  $g(t) = f(x + t\nu)$  is convex in  $t$  for any  $x \in \text{dom}f$  and  $\nu \in \mathbb{R}^n$ . Furthermore,

$$\text{dom}g = \left\{ t \in \mathbb{R} : x + t\nu \in \text{dom}f \right\}. \quad (6)$$

**Proof.** \_\_\_\_\_

We prove from both directions.

- (i)  $f$  **convex**  $\implies g$  **convex**: There are two sub-sections to prove -  $\text{dom}g$  is convex and  $g(\alpha t_1 + (1 - \alpha)t_2) \leq \alpha g(t_1) + (1 - \alpha)g(t_2)$ ,  $\forall \alpha \in (0, 1); t_1, t_2 \in \text{dom}g$ .

□.

### Proposition 1.2: Second Order Derivative Test
